

Relational Model

The relational model is based on the mathematical concept of a relation, which is physically represented as a table. A table is a matrix of a series of row and column intersections. Codd, a trained mathematician, used terminology taken from mathematics, principally set theory and predicate logic. In this section, the terminology and structural concepts of the relational model will be explained.

Data Structure of Relational Database

Following are the basic data structures used in relational database model.

- i. **Relation:** A relation is a table with columns and rows. It consists of all possible tuples.
- ii. **Tuple:** Single row of any relation is known as tuple.
- iii. **Attributes:** These are the characteristics of any relation.
- iv. **Domain:** Domain is the set of all permitted values or information about any attributes.
- v. **Tuple variable:** Tuple variable is the part of tuple or row, which is information or data stored in relation for any attribute.
- vi. **Degree:** Number of columns in any relation is known as its degree.
- vii. **Cardinality:** Number of rows in any relation is known as its cardinality.

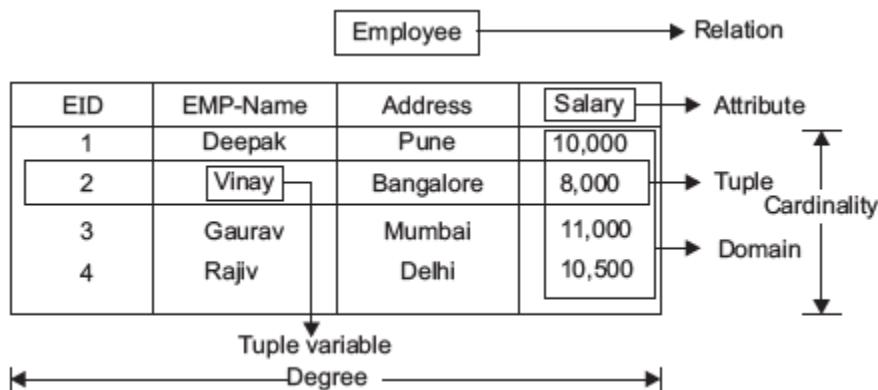

Fig 1: Basic data structures of relational database

Integrity Constraints

These are the rules or constraints applied to the database to keep data stable, accurate or consistent. To keep database consistent, we have to follow some rules known as integrity rules or integrity constraints.

a) Entity Integrity Rule (Integrity Rule 1)

Primary key or a part of it in any relation cannot be null. Suppose A is an attribute in relation R which is taken as primary key then A must not be null.

b) Referential Integrity Rule (Integrity Rule 2)

A foreign key can be either null or it can have only those values which are present in the primary key with which it is related. Suppose A is an attribute in relation R1, which is also the primary key in relation R2, then value of A in R1 should either be null or same as in relation R2.

Employee				Department	
EID	Name	Salary	Dept-ID	Dept-ID	Dept-Name
1	Amit	6,000	1A	1A	Accounts
2	Sumit	10,000	2C	2C	Computer
3	Lalit	15,000	4F	3E	Electrical
4	Deepak	9,000	3F	4C	Civil
5	Sandeep	4,000	—		

Null value is allowed

This is not allowed because Dept-ID is a foreign key and the value 4F is not present in attribute Dept-ID of relation Department.

Fig 2: Referential Integrity

c) Domain Constraints

The restrictions applied on domain are known as domain constraints. These restrictions are applied to every value of attribute. By following these constraints, the database is kept consistent. These restrictions include data types (integer, varchar, char, time format, date format etc.), size of variable, checks (like value not null etc.) etc.

Example. create table employee (Eid char (4), Name char (20),

Age integer (2), Salary integer,

primary key (Eid), Check (age>18))

Employee			
EID	Name	Age	Salary
1	Aditya	22	10,000
2	Dinesh	-18	5,600
3	Sumit	25	8,000
4	Lalit	20	ABC
5	Gaurav	23	11,000

Not allowed because age must be greater than 18
Not allowed because salary has integer data type

Fig 3: Domain Constraints

d) Key Constraints

In any relation R, if attribute A is primary key then A must have unique value or you can say that primary key attribute must have unique value. Duplicate values in primary key are invalid.

Employee		
EID	Name	Age
1	Aditya	22
2	Sumit	19
3	Deepak	25
2	Manoj	24
4	Dheeraj	28

Fig 4: Key Constraints

e) Tuple Uniqueness Constraints

In any relation R, all tuples in relation R must have distinct values. In other words, Duplicate tuples within a single relation are not allowed.

Employee		
EID	Name	Age
1	Aditya	22
2	Sumit	19
3	Deepak	25
2	Sumit	19
